## Definitions of Treatment Effects

- (ATE):  $\Delta^{\text{ATE}}(x) \equiv E(\Delta \mid X = x)$  where  $\Delta = Y_1 - Y_0$ .
- This is the effect of assigning treatment randomly to everyone of type  $X$  assuming full compliance, and ignoring general equilibrium effects.
- The average impact of treatment on persons who actually take the treatment is Treatment on the Treated (TT):  
 $\Delta^{\text{TT}}(x) \equiv E(\Delta \mid X = x, D = 1)$ .
- This parameter can also be defined conditional on  $P(Z)$ :  $\Delta^{\text{TT}}(x, p) \equiv E(\Delta \mid X = x, P(Z) = p, D = 1)$ .

- The mean effect of treatment on those for whom  $X = x$  and  $U_D = u_D$ : Marginal Treatment Effect (MTE)

$$\Delta^{\text{MTE}}(x, u_D) \equiv E(\Delta \mid X = x, U_D = u_D). \quad (1)$$

- Parameter defined independently of any instrument.
- Separate the definition of parameters from their identification.
- For  $u_D$  evaluation points close to zero,  $\Delta^{\text{MTE}}(x, u_D)$  is the expected effect of treatment on individuals with the value of unobservables that make them most likely to participate in treatment and who would participate even if the mean scale utility  $\mu_D(Z)$  is small. If  $U_D$  is large,  $\mu_D(Z)$  would have to be large to induce people to participate.

- Can also interpret  $E(\Delta \mid X = x, U_D = u_D)$  as the mean gain in terms of  $Y_1 - Y_0$  for persons with observed characteristics  $X$  who would be indifferent between treatment or not if they were randomly assigned a value of  $Z$ , say  $z$ , such that  $\mu_D(z) = V$ .

## LATE:

$$\begin{aligned} E(Y_1 - Y_0 \mid X = x, D(z) = 1, D(z') = 0) \\ = E(Y_1 - Y_0 \mid X = x, u'_D < U_D \leq u_D) = \Delta^{\text{LATE}}(x, u_D, u'_D) \end{aligned}$$

for  $u_D = \Pr(D(z) = 1) = P(z)$ ,  $u'_D = \Pr(D(z') = 1) = P(z')$ ,

- $\Pr(D(z) = 1) = \Pr(D = 1 \mid Z = z)$  and
- $\Pr(D(z') = 1) = \Pr(D = 1 \mid Z = z')$ .

- *Imbens and Angrist define the LATE parameter as the probability limit of an estimator.*
- Conflates issues of definition of parameters with issues of identification.
- This representation of LATE allows us to separate these two conceptually distinct matters and to define the LATE parameter more generally.
- One can, in principle, evaluate the right hand side of the preceding equation at any  $u_D, u'_D$  points in the unit interval and not only at points in the support of the distribution of the propensity score  $P(Z)$  conditional on  $X = x$  where it is identified.

**Table 1A:** Treatment effects and estimands as weighted averages of the marginal treatment effect

---

---

$$\text{ATE}(x) = E(Y_1 - Y_0 \mid X = x) = \int_0^1 \Delta^{\text{MTE}}(x, u_D) du_D$$

$$\text{TT}(x) = E(Y_1 - Y_0 \mid X = x, D = 1) = \int_0^1 \Delta^{\text{MTE}}(x, u_D) \omega_{\text{TT}}(x, u_D) du_D$$

$$\text{TUT}(x) = E(Y_1 - Y_0 \mid X = x, D = 0) = \int_0^1 \Delta^{\text{MTE}}(x, u_D) \omega_{\text{TUT}}(x, u_D) du_D$$

$$\text{PRTE}(x) = E(Y_{a'} \mid X = x) - E(Y_a \mid X = x) = \int_0^1 \Delta^{\text{MTE}}(x, u_D) \omega_{\text{PRTE}}(x, u_D) du_D$$

for two policies  $a$  and  $a'$  that affect the  $Z$  but not the  $X$

$$\text{IV}_J(x) = \int_0^1 \Delta^{\text{MTE}}(x, u_D) \omega_{\text{IV}}^J(x, u_D) du_D, \text{ given instrument } J$$

$$\text{OLS}(x) = \int_0^1 \Delta^{\text{MTE}}(x, u_D) \omega_{\text{OLS}}(x, u_D) du_D$$

---

Source: Heckman and Vytlacil (2005)

- All weights (except OLS) integrate up to 1
- **Exercise: Derive all weights and show they integrate to 1**

## Table 1B: Weights

$$\omega_{ATE}(x, u_D) = 1$$

$$\omega_{TT}(x, u_D) = \left[ \int_{u_D}^1 f_{P|X}(p | X = x) dp \right] \frac{1}{E(P | X = x)}$$

$$\omega_{TUT}(x, u_D) = \left[ \int_0^{u_D} f_{P|X}(p | X = x) dp \right] \frac{1}{E((1 - P) | X = x)}$$

$$\omega_{PRTE}(x, u_D) = \left[ \frac{F_{P_{a'}|X}(u_D|x) - F_{P_a|X}(u_D|x)}{\Delta \bar{P}(x)} \right], \text{ where } \Delta \bar{P}(x) = E(P_a | X = x) - E(P_{a'} | X = x)$$

$$\omega_{IV}^J(x, u_D) = \left[ \int_{u_D}^1 \int (J(Z) - E(J(Z) | X = x)) f_{J,P|X}(j, t | X = x) dj dt \right] \frac{1}{\text{Cov}(J(Z), D | X = x)}$$

$$\omega_{OLS}(x, u_D) = 1 + \frac{E(U_1 | X = x, U_D = u_D) \omega_1(x, u_D) - E(U_0 | X = x, U_D = u_D) \omega_0(x, u_D)}{\Delta^{MTE}(x, u_D)}$$

$$\omega_1(x, u_D) = \left[ \int_{u_D}^1 f_{P|X}(p | X = x) dp \right] \frac{1}{E(P | X = x)}$$

$$\omega_0(x, u_D) = \left[ \int_0^{u_D} f_{P|X}(p | X = x) dp \right] \frac{1}{E((1 - P) | X = x)}$$

Source: Heckman and Vytlacil (2005)

- $\Delta^{\text{LATE}}(x, u_D, u'_D)$  is continuous in  $u_D$  and  $u'_D$  and  
$$\lim_{u'_D \uparrow u_D} \Delta^{\text{LATE}}(x, u_D, u'_D) = \Delta^{\text{MTE}}(x, u_D).$$

$$\text{Treatment Parameter } (j) = \int_0^1 \Delta^{\text{MTE}}(x, u_D) \omega_j(x, u_D) du_D$$

- $\omega_j(x, u_D)$  is the weighting function for the MTE.
- Integral is defined over the full support of  $u_D$ .
- Except for the OLS weights, the weights in the table all integrate to one, although in some cases the weights for IV may be negative.

$\Delta^{\text{TT}}(x)$  is weighted average of  $\Delta^{\text{MTE}}$ :

$$\Delta^{\text{TT}}(x) = \int_0^1 \Delta^{\text{MTE}}(x, u_D) \omega_{\text{TT}}(x, u_D) du_D,$$

where

$$\omega_{\text{TT}}(x, u_D) = \frac{1 - F_{P|X}(u_D | x)}{\int_0^1 (1 - F_{P|X}(t | x)) dt} = \frac{S_{P|X}(u_D | x)}{E(P(Z) | X = x)}, \quad (2)$$

and  $S_{P|X}(u_D | x)$  is  $\Pr(P(Z) > u_D | X = x)$  and  $\omega_{\text{TT}}(x, u_D)$  is a weighted distribution.

- $\Delta^{TT}(x)$  oversamples  $\Delta^{MTE}(x, u_D)$  for those individuals with low values of  $u_D$  that make them more likely to participate in the program being evaluated.
- Treatment on the untreated (TUT) is defined symmetrically with TT and oversamples those least likely to participate. The various weights are displayed in table 1AB.
- The other weights, treatment effects and estimands shown in this table are discussed later.

- Observe that if
 
$$E(Y_1 - Y_0 \mid X = x, U_D = u_D) = E(Y_1 - Y_0 \mid X = x)$$
 so  $\Delta = Y_1 - Y_0$  is mean independent of  $U_D$  given  $X = x$ , then
 
$$\Delta^{\text{MTE}} = \Delta^{\text{ATE}} = \Delta^{\text{TT}} = \Delta^{\text{LATE}}.$$
- Where there is no heterogeneity in terms of unobservables in MTE ( $\Delta$  constant conditional on  $X = x$ ) or agents do not act on it so that  $U_D$  drops out of the conditioning set, marginal treatment effects are average treatment effects, so that all of the evaluation parameters are the same.
- Otherwise, they are different.
- Only in the case where the marginal treatment effect is the average treatment effect will the “effect” of treatment be uniquely defined.

**Figure 1A:** Weights for the marginal treatment effect for different parameters

Source: Heckman and Vytlačil (2005)

- A high  $u_D$  is associated with higher cost, relative to return, and less likelihood of choosing  $D = 1$ .
- The decline of MTE in terms of higher values of  $u_D$  means that people with higher  $u_D$  have lower gross returns.
- TT overweights low values of  $u_D$  (i.e., it oversamples  $U_D$  that make it likely to have  $D = 1$ ).
- ATE samples  $U_D$  uniformly.
- Treatment on the Untreated ( $E(Y_1 - Y_0 | X = x, D = 0)$ ), or TUT, oversamples the values of  $U_D$  which make it unlikely to have  $D = 1$ .

**Table 3:** Treatment parameters and estimands in the generalized Roy example

Treatment on the Treated	0.2353
Treatment on the Untreated	0.1574
Average Treatment Effect	0.2000
Sorting Gain <sup>a</sup>	0.0353
Policy Relevant Treatment Effect (PRTE)	0.1549
Selection Bias <sup>b</sup>	-0.0628
Linear Instrumental Variables <sup>c</sup>	0.2013
Ordinary Least Squares	0.1725

$$^a TT - ATE = E(Y_1 - Y_0 \mid D = 1) - E(Y_1 - Y_0)$$

$$^b OLS - TT = E(Y_0 \mid D = 1) - E(Y_0 \mid D = 0)$$

<sup>c</sup>Using Propensity Score  $P(Z)$  as the instrument.

Note: The model used to create Table 3 is the same as those used to create Figures 1A and 1A. The PRTE is computed using a policy  $t$  characterized as follows: If  $Z > 0$  then  $D = 1$  if  $Z(1 + t) - V \geq 0$ . If  $Z \leq 0$  then  $D = 1$  if  $Z - V \geq 0$ . For this example  $t$  is set equal to 0.2.

Source: Heckman and Vytlacil (2005)

- Table 3 shows the treatment parameters produced from the different weighting schemes for the model used to generate the weights in figures 1A and 1B (next).
- Given the decline of the MTE in  $u_D$ , it is not surprising that  $TT > ATE > TUT$ . This is the generalized Roy version of the principle of diminishing returns.
- Those most likely to self select into the program benefit the most from it. The difference between TT and ATE is a sorting gain:  $E(Y_1 - Y_0 | X, D = 1) - E(Y_1 - Y_0 | X)$ , the average gain experienced by people who sort into treatment compared to what the average person would experience.
- Purposive selection on the basis of gains should lead to positive sorting gains of the kind found in the table. If there is negative sorting on the gains, then  $TUT \geq ATE \geq TT$ .

**Figure 1B:** Marginal Treatment Effect vs Linear Instrumental Variables and Ordinary Least Squares Weights

$$Y_1 = \alpha + \bar{\beta} + U_1$$

$$Y_0 = \alpha + U_0$$

$$D = 1 \text{ if } Z - V \geq 0$$

$$U_1 = \sigma_1 \tau$$

$$U_0 = \sigma_0 \tau$$

$$V = \sigma_V \tau$$

$$U_D = \Phi\left(\frac{V}{\sigma_V \sigma_\tau}\right)$$

$$\alpha = 0.67$$

$$\bar{\beta} = 0.2$$

$$\tau \sim N(0, 1)$$

$$\sigma_1 = 0.012$$

$$\sigma_0 = -0.050$$

$$\sigma_V = -1.000$$

$$Z \sim N(-0.0026, 0.2700)$$

Source: Heckman and Vytlacil (2005).

- The representations of treatment effects defined in Table 1A remain valid even if  $Z$  is not independent of  $U_D$
- If there are no variables in  $Z$  that are not also contained in  $X$ , or if a more general nonseparable choice model generates  $D$  (so  $D^* = \mu_D(Z, U_D)$ ).
- No instrument  $Z$  is needed to define the parameters (task 1: theory).
- Instrument needed to *identify* parameters.

## Appendix: Derivations of Weights

- Given the index structure of the Generalized Roy Model, a simple relationship exists among the parameters.
- From the definitions  $D = \mathbf{1}(U_D \leq P(z))$  and  $\Delta = Y_1 - Y_0$  that
$$\Delta^{TT}(x, P(z)) = E(\Delta | X = x, U_D \leq P(z)). \quad (3)$$

- Next consider  $\Delta^{\text{LATE}}(x, P(z), P(z'))$ .
- Note that  $E(Y|X = x, P(Z) = P(z))$

$$\begin{aligned}
 &= P(z) \left[ E(Y_1|X = x, P(Z) = P(z), D = 1) \right] \\
 &+ (1 - P(z)) \left[ E(Y_0|X = x, P(Z) = P(z), D = 0) \right] \\
 &= \int_0^{P(z)} E(Y_1|X = x, U_D = u_D) du_D + \int_{P(z)}^1 E(Y_0|X = x, U_D = u_D) du_D,
 \end{aligned}$$

Thus

$$\begin{aligned} & E(Y|X = x, P(Z) = P(z)) - E(Y|X = x, P(Z) = P(z')) \\ &= \int_{P(z')}^{P(z)} E(Y_1|X = x, U_D = u_D) du_D - \int_{P(z')}^{P(z)} E(Y_0|X = x, U_D = u_D) du_D. \end{aligned}$$

Thus

$$\Delta^{\text{LATE}}(x, P(z), P(z')) = E(\Delta | X = x, P(z') \leq U_D \leq P(z)).$$

- Notice that this expression could be taken as an alternative definition of LATE.
- Note that, in this expression, we could replace  $P(z)$  and  $P(z')$  with  $u_D$  and  $u'_D$ .
- *No instrument needs to be available to define LATE.*

- We write these relationships in succinct form:

$$\Delta^{\text{MTE}}(x, u_D) = E(\Delta | X = x, U_D = u_D)$$

$$\Delta^{\text{ATE}}(x) = \int_0^1 E(\Delta | X = x, U_D = u_D) du_D$$

$$P(z)[\Delta^{\text{TT}}(x, P(z))] = \int_0^{P(z)} E(\Delta | X = x, U_D = u_D) du_D$$

$$(P(z) - P(z'))[\Delta^{\text{LATE}}(x, P(z), P(z'))] =$$

$$\int_{P(z')}^{P(z)} E(\Delta | X = x, U_D = u_D) du_D. \quad (4)$$

- The relationship between MTE and LATE or TT conditional on  $P(z)$  is analogous to the relationship between a probability density function and a cumulative distribution function.
- The probability density function and the cumulative distribution function represent the same information, but for some purposes the density function is more easily interpreted.
- Likewise, knowledge of TT for all  $P(z)$  evaluation points is equivalent to knowledge of the MTE for all  $u_D$  evaluation points, so it is not the case that knowledge of one provides more information than knowledge of the other.
- However, in many choice-theoretic contexts it is often easier to interpret MTE than the TT or LATE parameters.
- It has the interpretation as a measure of willingness to pay on the part of people on a specified margin of participation in the program.

- $\Delta^{\text{MTE}}(x, u_D)$  is the average effect for people who are just indifferent between participation in the program ( $D = 1$ ) or not ( $D = 0$ ) if the instrument is externally set so that  $P(Z) = u_D$ .
- For values of  $u_D$  close to zero,  $\Delta^{\text{MTE}}(x, u_D)$  is the average effect for individuals with unobservable characteristics that make them the most inclined to participate in the program ( $D = 1$ ).
- For values of  $u_D$  close to one it is the average treatment effect for individuals with unobserved (by the econometrician) characteristics that make them the least inclined to participate.
- ATE integrates  $\Delta^{\text{MTE}}(x, u_D)$  over the entire support of  $U_D$  (from  $u_D = 0$  to  $u_D = 1$ ). It is the average effect for an individual chosen at random from the entire population.

- $\Delta^{TT}(x, P(z))$  is the average treatment effect for persons who chose to participate at the given value of  $P(Z) = P(z)$ ;
- It integrates  $\Delta^{MTE}(x, u_D)$  up to  $u_D = P(z)$ .
- As a result, it is primarily determined by the MTE parameter for individuals whose unobserved characteristics make them the most inclined to participate in the program.
- LATE is the average treatment effect for someone who would not participate if  $P(Z) \leq P(z')$  and would participate if  $P(Z) \geq P(z)$ .
- The parameter  $\Delta^{LATE}(x, P(z), P(z'))$  integrates  $\Delta^{MTE}(x, u_D)$  from  $u_D = P(z')$  to  $u_D = P(z)$ .

- Use the third expression in equation (4)
- Substitute into equation (3)
- We obtain an alternative expression for the TT parameter as a weighted average of MTE parameters:

$$\begin{aligned} \Delta^{\text{TT}}(x) &= \int_0^1 \frac{1}{p} \left[ \int_0^p E(\Delta | X = x, U_D = u_D) du_D \right] dF_{P(Z)|X,D}(p|x, D = 1). \end{aligned}$$

Using Bayes' rule, it follows that

$$dF_{P(Z)|X,D}(p|x, 1) = \frac{\Pr(D = 1|X = x, P(Z) = p)}{\Pr(D = 1|X = x)} dF_{P(Z)|X}(p|x).$$

- Since  $\Pr(D = 1|X = x, P(Z) = p) = p$ , it follows that

$$\Delta^{TT}(x) = \frac{1}{\Pr(D = 1|X = x)} \int_0^1 \left( \int_0^p E(\Delta|X = x, U_D = u_D) du_D \right) dF_{P(Z)|X}(p|x). \quad (5)$$

- Note that

$$\Pr(D = 1|X = x) = E(P(Z)|X = x) = \int_0^1 (1 - F_{P(Z)|X}(t|x)) dt.$$

- Reinterpret (5) as a weighted average of local IV parameters where the weighting is similar to that obtained from a length-biased, size-biased, or  $P$ -biased sample:

$$\begin{aligned}
 \Delta^{\text{TT}}(x) &= \frac{1}{\Pr(D = 1|X = x)} \quad x \int_0^1 \left( \int_0^1 \mathbf{1}(u_D \leq p) E(\Delta|X = x, U_D = u_D) du_D \right) dF_{P(Z)|X}(p|x) \\
 &= \frac{1}{\int (1 - F_{P(Z)|X}(t|x)) dt} \int_0^1 \left( \int_0^1 E(\Delta|X = x, U_D = u_D) \mathbf{1}(u_D \leq p) dF_{P(Z)|X}(p|x) \right) du_D \\
 &= \int_0^1 E(\Delta|X = x, U_D = u_D) \left( \frac{1 - F_{P(Z)|X}(u_D|x)}{\int (1 - F_{P(Z)|X}(t|x)) dt} \right) du_D \\
 &= \int_0^1 E(\Delta|X = x, U_D = u_D) g_x(u_D) du_D
 \end{aligned}$$

Where

$$g_x(u_D) = \frac{1 - F_{P(Z)|X}(u_D|x)}{\int (1 - F_{P(Z)|X}(t|x)) dt}$$

- $g_x(u_D)$  is a *weighted distribution*.
- Since  $g_x(u_D)$  is a non-increasing function of  $u_D$ , drawings from  $g_x(u_D)$  oversample persons with low values of  $U_D$ , i.e., values of unobserved characteristics that make them the most likely to participate in the program no matter what their value of  $P(Z)$ .

Since

$$\Delta^{\text{MTE}}(x, u_D) = E(\Delta | X = x, U_D = u_D)$$

it follows that

$$\Delta^{\text{TT}}(x) = \int_0^1 \Delta^{\text{MTE}}(x, u_D) g_x(u_D) du_D.$$

- The TT parameter is thus a weighted version of MTE, where  $\Delta^{\text{MTE}}(x, u_D)$  is given the largest weight for low  $u_D$  values and is given zero weight for  $u_D \geq p_x^{\text{max}}$ , where  $p_x^{\text{max}}$  is the maximum value in the support of  $P(Z)$  conditional on  $X = x$ .

**Figure 3:** MTE integrates to ATE and TT under full support (for dichotomous outcome)

Source: Heckman and Vytlacil (2000).

- The curve is the MTE parameter as a function of  $u_D$ , and is drawn for the special case where the outcome variable is binary so that MTE parameter is bounded between  $-1$  and  $1$ .

- The ATE parameter averages  $\Delta^{\text{MTE}}(u_D)$  over the full unit interval (i.e., is the area under A minus the area under B and C in the figure).
- $\Delta^{\text{TT}}(P(z))$  averages  $\Delta^{\text{MTE}}(u_D)$  up to the point  $P(z)$  (is the area under A minus the area under B in the figure).
- Because  $\Delta^{\text{MTE}}(u_D)$  is assumed to be declining in  $u_D$ , the TT parameter for any given  $P(z)$  evaluation point is larger than the ATE parameter.

- Equation (4) relates each of the other parameters to the MTE parameter. One can also relate each of the other parameters to the LATE parameter.

- MTE is the limit form of LATE:

$$\Delta^{\text{MTE}}(x, p) = \lim_{p' \rightarrow p} \Delta^{\text{LATE}}(x, p, p').$$

- Relationship between LATE and ATE is immediate:

$$\Delta^{\text{ATE}}(x) = \Delta^{\text{LATE}}(x, 0, 1).$$

- Using Bayes' rule, the relationship between LATE and TT is

$$\Delta^{\text{TT}}(x) = \int_0^1 \Delta^{\text{LATE}}(x, 0, p) \frac{p}{\Pr(D = 1|X = x)} dF_{P(Z)|X}(p|x). \quad (6)$$

## Policy Relevant Treatment Effect

- The conventional treatment parameters do not always answer economically interesting questions. Their link to cost-benefit analysis and interpretable economic frameworks is sometimes obscure.
- Each answers a different question. Many investigators estimate a treatment effect and hope that it answers an interesting question.
- A more promising approach for defining parameters is to postulate a policy question or decision problem of interest and to derive the treatment parameter that answers it.
- Taking this approach does not in general produce the conventional treatment parameters or the estimands produced from instrumental variables.

- Consider a class of policies that affect  $P$ , the probability of participation in a program, but do not affect  $\Delta^{\text{MTE}}$ . The policies analyzed in the treatment effect literature that change the  $Z$  not in  $X$  are more restrictive than the general policies that shift  $X$  and  $Z$  analyzed in the structural literature.
- An example from the schooling literature would be policies that change tuition or distance to school but do not directly affect the gross returns to schooling (Card, 2001). Since we ignore general equilibrium effects in this chapter, the effects on  $(Y_0, Y_1)$  from changes in the overall level of education are assumed to be negligible.

- Let  $p$  and  $p'$  denote two potential policies and let  $D_p$  and  $D_{p'}$  denote the choices that would be made under policies  $p$  and  $p'$ . When we discuss the Policy Relevant Treatment Effect, we use “ $p$ ” to denote the policy and distinguish it from the realized value of  $P(Z)$ .
- Under our assumptions, the policies affect the  $Z$  given  $X$ , but not the potential outcomes.

- Let the corresponding decision rules be  $D_p = \mathbf{1}[P_p(Z_p) \geq U_D]$ ,  $D_{p'} = \mathbf{1}[P_{p'}(Z_{p'}) \geq U_D]$ , where  $P_p(Z_p) = \Pr(D_p = 1 \mid Z_p)$  and  $P_{p'}(Z_{p'}) = \Pr(D_{p'} = 1 \mid Z_{p'})$ .
- To simplify the exposition, we will suppress the arguments of these functions and write  $P_p$  and  $P_{p'}$  for  $P_p(Z_p)$  and  $P_{p'}(Z_{p'})$ . Define  $(Y_{0,p}, Y_{1,p}, U_{D,p})$  as  $(Y_0, Y_1, U_D)$  under policy  $p$ , and define  $(Y_{0,p'}, Y_{1,p'}, U_{D,p'})$  correspondingly under policy  $p'$

- Assume that  $Z_p$  and  $Z_{p'}$  are independent of  $(Y_{0,p}, Y_{1,p}, U_{D,p})$  and  $(Y_{0,p'}, Y_{1,p'}, U_{D,p'})$  respectively, conditional on  $X_p$  and  $X_{p'}$ . Let  $Y_p = D_p Y_{1,p} + (1 - D_p) Y_{0,p}$  and  $Y_{p'} = D_{p'} Y_{1,p'} + (1 - D_{p'}) Y_{0,p'}$  denote the outcomes that would be observed under policies  $p$  and  $p'$ , respectively.
- Assume  $\Delta^{\text{MTE}}$  is policy invariant.

- PRTE, denoted  $\Delta^{\text{PRTE}}(x)$ :

$$\begin{aligned}
 & E(Y_p | X = x) - E(Y_{p'} | X = x) \\
 &= \int_0^1 \Delta^{\text{MTE}}(x, u_D) \{F_{P_{p'}|X}(u_D | x) - F_{P_p|X}(u_D | x)\} du_D, \quad (7)
 \end{aligned}$$

where  $F_{P_p|X}(\cdot | x)$  and  $F_{P_{p'}|X}(\cdot | x)$  are the distributions of  $P_p$  and  $P_{p'}$  conditional on  $X = x$

- Defined for the different policy regimes and  $\Delta_{\Upsilon}^{\text{MTE}}(x, u_D) = E(\Upsilon(Y_{1,p}) - \Upsilon(Y_{0,p}) | U_{D,p} = u_D, X_p = x)$ .

- The weights in expression (7) are derived under the assumption that the policy does not change the joint distribution of outcomes.
- To simplify the notation, throughout the rest of this chapter when we discuss PRTE, we assume that  $\Upsilon(Y) = Y$ . Modifications of our analysis for the more general case are straightforward.

- Define  $\Delta\bar{P}(x) = E(P_p | X = x) - E(P_{p'} | X = x)$ , the change in the proportion of people induced into the program due to the intervention. Assuming  $\Delta\bar{P}(x)$  is positive, we may define per person affected weights as
$$\omega_{\text{PRTE}}(x, u_D) = \frac{F_{P_{p'}|X}(u_D|x) - F_{P_p|X}(u_D|x)}{\Delta\bar{P}(x)}.$$

# Derivation of PTRE

## Proof.

**(Equation (7))** Define  $\mathbf{1}_{\mathcal{P}}(t)$  to be the indicator function for the event  $t \in \mathcal{P}$ . Then  $E(Y_p | X)$

$$\begin{aligned} &= \int_0^1 E(Y_p | X, P_p(Z_p) = t) dF_{P_p|X}(t) \\ &= \int_0^1 \left[ \int_0^1 [\mathbf{1}_{[0,t]}(u_D) E(Y_{1,p} | X, U_D = u_D) + \mathbf{1}_{(t,1]}(u_D) E(Y_{0,p} | X, U_D = u_D)] du_D \right] dF_{P_p|X}(t) \\ &= \int_0^1 \left[ \int_0^1 [\mathbf{1}_{[u_D,1]}(t) E(Y_{1,p} | X, U_D = u_D) + \mathbf{1}_{(0,u_D]}(t) E(Y_{0,p} | X, U_D = u_D)] dF_{P_p|X}(t) \right] du_D \\ &= \int_0^1 \left[ (1 - F_{P_p|X}(u_D)) E(Y_{1,p} | X, U_D = u_D) + F_{P_p|X}(u_D) E(Y_{0,p} | X, U_D = u_D) \right] du_D. \end{aligned}$$

This derivation involves changing the order of integration. *Q.E.D.*

- This derivation involves changing the order of integration.
- Note that from (A-4),

$$E|\mathbf{1}_{[0,t]}(u_D)E(Y_{1,p} | X, U_D = u_D) + \mathbf{1}_{(t,1]}(u_D)E(Y_{0,p} | X, U_D = u_D)| \leq E(|Y_1| + |Y_0|) < \infty$$

so the change in the order of integration is valid by Fubini's theorem.

- Comparing policy  $p$  to policy  $p'$ ,

$$\begin{aligned} & E(Y_p | X) - E(Y_{p'} | X) \\ &= \int_0^1 E(\Delta | X, U_D = u_D)(F_{P_{p'}|X}(u_D) - F_{P_p|X}(u_D)) du_D, \end{aligned}$$
