1. Introduction

2. Key Patterns in the Data

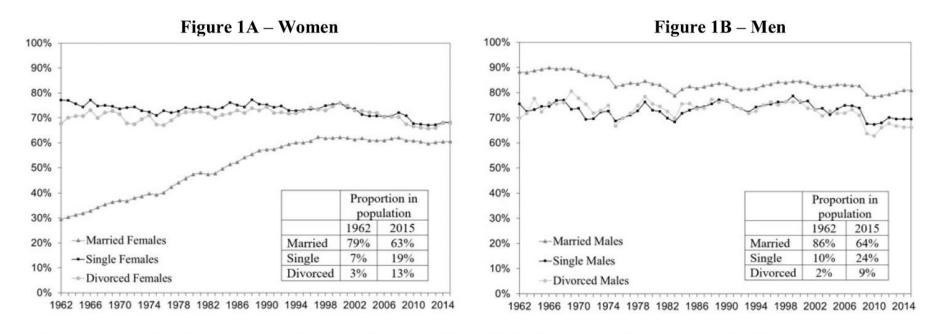

FIGURE 1.—Employment rate by marital status: 1962–2015. *Note*: Fraction employed of the Caucasian population aged 22–65. We define employed as working at least 10 hours a week.

Figure 2A – Women 50 Annual Growth Rate 1962-2015 45 Married 1.8% 1.2% Single 40 Divorced 1.7% 35 30 25 20 -Married Women -Single Women -Divorced Women 1962 1966 1970 1974 1978 1982 1986 1990 1994 1998 2002 2006 2010 2014

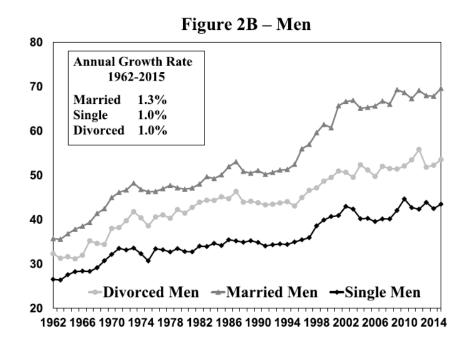

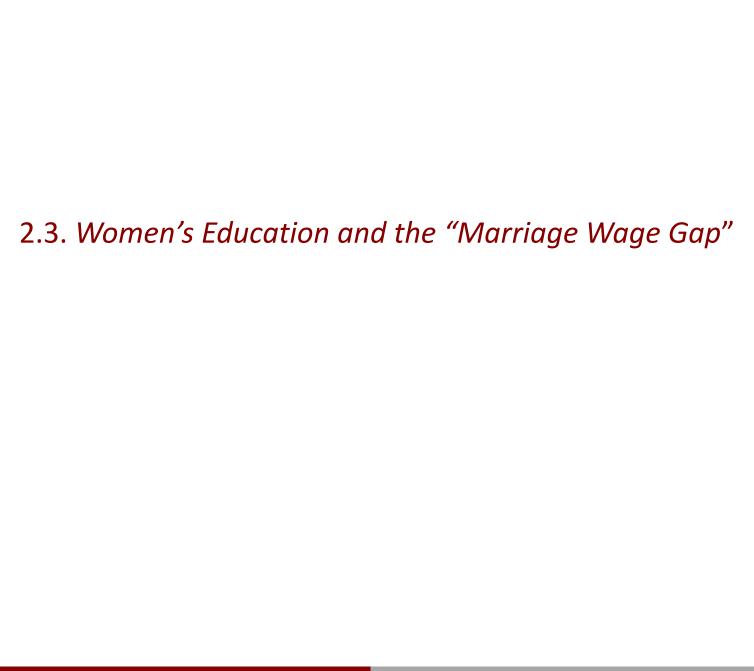

FIGURE 2.—Annual wages by marital status: 1962—2015. *Note*: Real annual wages (in thousands of dollars) of full-time full-year Caucasian workers aged 22–65 (2012 prices). For details, see Appendix A.

3. A Life-cycle Model of Education, Labor Supply, Marriage/Divorce, and Fertility

Married couples have total gross income GY_t^M given by the equation

$$GY_t^M = (w_t^m h_t^m + w_t^f h_t^f) + b_m I[h_t^m = 0] + b_f I[h_t^f = 0].$$
 (1)

Here w_t^j and h_t^j for j = f, m are annual full-time wage rates and the b_j are unemployment benefits plus values of home production. We will use the M superscript throughout to indicate values for married individuals. Net income is Y_t^M given by the equation

$$Y_{t}^{M} = GY_{t}^{M} - \tau_{t}^{M} ((w_{t}^{m} h_{t}^{m} + w_{t}^{f} h_{t}^{f}), N_{t}), \tag{2}$$

where $\tau_t^M(\cdot,\cdot)$ is the tax function for married couples based on the time t tax rules.

$$C_t^M = (1 - \kappa(N_t)) Y_t^M. \tag{3}$$

Here $\kappa(N_t)$ is the fraction of Y_t^M spent on children, based on a square root equivalence scale.

The period utility of a married person of age t and gender j in state Ω_{jt} is given by

$$U_{t}^{jM}(\Omega_{jt}) = \frac{1}{\alpha} (\psi C_{t}^{M})^{\alpha} + L_{jt}(l_{t}^{j}) + \theta_{t}^{M} + \pi_{t}^{M} p_{t}$$

$$+ A_{j}^{M} Q(l_{t}^{f}, l_{t}^{m}, Y_{t}^{M}, N_{t}), \quad j = m, f,$$
(4a)

$$L_{jt}(l_t^j) = \frac{\beta_{jt}}{\gamma} (l_t^j)^{\gamma} + \mu_{jt} l_t^j, \quad \gamma < 1, \alpha < 1.$$
 (4b)

This is denoted by $\mu_{jt}l_t^j$, where μ_{jt} is a random variable. Our specification of the stochastic process for μ_{jt} is an important and novel aspect of our model. Specifically, we assume that

$$\ln(\mu_{jt}) = \tau_{0j} + \tau_{1j} \ln(\mu_{j,t-1}) + \tau_{2j} p_{t-1} + \varepsilon_{jt}^{l} \quad \text{where } \varepsilon_{jt}^{l} \sim \text{iidN}(0, \sigma_{\varepsilon}^{l}), \tag{5}$$

where $0 < \tau_{1j} < 1$.

$$\theta_t^M = d_1 + d_2 \cdot I[E^m - E^f > 0] + d_3 \cdot I[E^f - E^m > 0] + d_4 (H_t^m - H_t^f)^2 + \varepsilon_t^M, \tag{6}$$

where $\varepsilon_t^M \sim \text{iidN}(0, \sigma_\varepsilon^M)$ and E^j denotes education, rank ordered as high school dropout (HSD), high school (HSG), some college (SC), college (CG), and post-college (PC), and $H_t^j \in \{1, 2, 3\}$ denotes health (i.e., good, fair, or poor).

Next, consider the utility from pregnancy, π_t . We specify that

$$\pi_{t} = \pi_{1} M_{t} + \pi_{2} H_{ft} + \pi_{3} N_{t} + \pi_{4} p_{t-1} + \varepsilon_{t}^{p} + \exp(\varepsilon_{t}^{up}), \tag{7}$$

where $\varepsilon_t^p \sim \mathrm{iidN}(0, \sigma_\varepsilon^p)$ and $\varepsilon_t^{up} \sim \mathrm{iidN}(pr, 1)$.

Finally, consider the function $Q(\cdot)$ that determines the utility a couple receives from the quality and quantity of children. We assume it is a CES function of the inputs, as follows:

$$Q(l_t^f, l_t^m, Y_t^M, N_t) = (a_f(l_t^f)^\rho + a_m(l_t^m)^\rho + a_g(\kappa(N_t)Y_t^M)^\rho + (1 - a_f - a_m - a_g)N_t^\rho)^{1/\rho}.$$
(8)

We are now able to write the choice-specific value functions for married *individuals*. These depend on both a person's own state and that of their partner:

$$V_{t}^{jM}(l_{t}^{m}, l_{t}^{f}, p_{t} | \Omega_{mt}, \Omega_{ft})$$

$$= \frac{1}{\alpha} (\psi C_{t}^{M})^{\alpha} + L(l_{t}^{j}) + \theta_{t}^{M} + \pi_{t} p_{t} + A_{j}^{M} Q(l_{t}^{f}, l_{t}^{f}, Y_{t}^{M}, N_{t})$$

$$+ \delta E_{\text{MAX}} (M_{t+1} V_{t+1}^{jM} (\Omega_{m,t+1}, \Omega_{f,t+1}) + (1 - M_{t+1}) V_{t+1}^{j} (\Omega_{j,t+1})), \quad j = f, m.$$
(9)

In our collective model, the household value function is given by

$$V_t^M(l_t^m, l_t^f, p_t \mid \Omega_{mt}, \Omega_{ft}) = \lambda V_t^{fM}(l_t^m, l_t^f, p_t \mid \Omega_{mt}, \Omega_{ft}) + (1 - \lambda) V_t^{mM}(l_t^m, l_t^f, p_t \mid \Omega_{mt}, \Omega_{ft}).$$

$$(10)$$

$$V_t^{jM}(l_t^m, l_t^f, p_t \mid \Omega_{mt}, \Omega_{ft}) \ge V_t^j(\Omega_{jt}) - \Delta_{jt} \quad \text{for } j = f, m,$$
(11)

where Δ_{it} is the cost of divorce.¹⁷ If $\mathcal{F} = \emptyset$, no choice vector $\{l_t^m, l_t^f, p_t\}$ satisfies (11).

$$\left\{l_{t}^{m*}, l_{t}^{f*}, p_{t}^{*}\right\} = \begin{cases} \arg\max_{\{l_{t}^{m}, l_{t}^{f}, p_{t}\} \in \mathcal{F}} V_{t}^{M}\left(l_{t}^{m}, l_{t}^{f}, p_{t} \mid \Omega_{mt}, \Omega_{ft}\right) & \text{if } \mathcal{F} \neq \emptyset, \\ \emptyset & \text{if } \mathcal{F} = \emptyset. \end{cases}$$

The form of (10) ensures that $\{l_t^{m*}, l_t^{f*}, p_t^*\}$ is a Pareto efficient allocation. If one or more parties prefer to remain single for all possible $\{l_t^m, l_t^f, p_t\}$, then $\mathcal{F} = \emptyset$ and a divorce occurs. The maximized value function of a married *individual* in state Ω_{jt} is given by

$$V_t^{jM}(\Omega_{mt}, \Omega_{ft}) \equiv \begin{cases} V_t^{jM} \left(l_t^{m*}, l_t^{f*}, p_t^* \mid \Omega_{mt}, \Omega_{ft} \right) & \text{for } j = f, m \text{ if } \mathcal{F} \neq \emptyset, \\ -\infty & \text{for } j = f, m \text{ if } \mathcal{F} = \emptyset. \end{cases}$$
(12)

$$Y_t^j = GY_t^j - \tau_t^S(w_t^j h_t^j, N_t), \quad j = f, m,$$
 (14)

where $\tau_t^S(w_t^j h_t^j, N_t)$ is the time t tax function for single individuals calculated using the tax rules described in Appendix B. Thus, the budget constraint for a single person is simply

$$C_t^j = (1 - \kappa(N_t))Y_t^j. \tag{15}$$

Note that both single men and women may have children ($N_t > 0$). These may be children from a previous marriage or, in the case of single women, children born outside of marriage.

$$U_t^f(\Omega_{ft}) = \left(\frac{1}{\alpha}(C_t)^{\alpha} + L_j(l_t)\right)(1 - s_t) + \vartheta_{ft}s_t + \pi_t p_t + A_f^s Q(l_t, 0, Y_t, N_t), \tag{16}$$

where s_t is a 1/0 indicator for school attendance. Provided the single woman is not in

$$\vartheta_{jt} = \vartheta_{0j} + TC \cdot I(E_t > HSG) + \vartheta_{1j}PE + \vartheta_{2j}\mu_j^W \quad \text{for } j = m, f.$$
 (17)

Here ϑ_{jt} is a function of tuition cost TC, which is only relevant for higher education, the skill endowment μ_j^W , and parents' education, denoted PE.

We can now write the choice-specific value functions for single females:

$$V_{t}^{f}(l_{t}, p_{t}, s_{t} | \Omega_{ft}) = \left(\frac{1}{\alpha}(C_{t})^{\alpha} + L_{f}(l_{t})\right)(1 - s_{t}) + \vartheta_{ft}s_{t} + \pi_{t}p_{t} + A_{f}^{s}Q(l_{t}, 0, Y_{t}, N_{t}) + \delta E_{\text{MAX}}V(\Omega_{f,t+1}),$$
(18a)

$$E_{\text{MAX}}V(\Omega_{f,t+1}) = E_{\text{MAX}}(M_{t+1}V_{t+1}^{fM}(\Omega_{m,t+1}, \Omega_{f,t+1}) + (1 - M_{t+1})V_{t+1}^{f}(\Omega_{f,t+1})),$$
(18b)

where $E_{\text{MAX}}V(\Omega_{f,t+1})$ takes into account that the person may get married at t+1. Similarly, for single males, we have the choice-specific value function:

$$V_{t}^{m}(l_{t}, s_{t} \mid \Omega_{mt}) = \left(\frac{1}{\alpha}(C_{t})^{\alpha} + L_{m}(l_{t})\right)(1 - s_{t}) + \vartheta_{mt}s_{t} + A_{m}^{s}Q(0, l_{t}, Y_{t}, N_{t}) + \delta E_{\text{MAX}}V(\Omega_{m, t+1}).$$
(19)

To proceed, for women and men we have, respectively,

$$V_t^f(\Omega_{ft}) = \max_{\{l_t, p_t, s_t\} \in \mathcal{S}_t^f} V_t^f(l_t, p_t, s_t \mid \Omega_{ft}),$$
(20)

$$V_t^m(\Omega_{mt}) = \max_{\{l_t, s_t\} \in \mathcal{S}_t^m} V_t^f(l_t, s_t \mid \Omega_{mt}). \tag{21}$$

The wage offer functions have a standard Ben-Porath (1967), Mincer (1974) form:

$$\ln w_{et}^{j} = \omega_{1e}^{j} + \omega_{2e}^{j} X_{t} - \omega_{3e}^{j} X_{t}^{2} + \varepsilon_{jt}^{W} \quad \text{for } j = f, m,$$
 (22)

where X_t is work experience (years) and $e \in \{HSD, HSG, SC, CG, PC\}$ is education level.

The error term ε_{it}^W in equation (22) has a permanent/transitory structure:

$$\varepsilon_{jt}^{W} = \mu_{j}^{W}(PE) + \tilde{\varepsilon}_{jt}^{W} \quad \text{where } \tilde{\varepsilon}_{jt}^{W} \sim \text{iidN}(0, \sigma_{\varepsilon}^{W}).$$
 (23)

$$P_{j}(k \in D_{t}) = \frac{\exp(\phi_{j0k} + \phi_{j1k}e_{t}^{r} + \phi_{j2k}X_{t} + \phi_{j3k}H_{t})}{1 + \exp(\phi_{j0k} + \phi_{j1k}e_{t}^{r} + \phi_{j2k}X_{t} + \phi_{j3k}H_{t})} \quad \text{for } k = 1, 2,$$
 (24)

where k = 1, 2 denote full- and part-time, respectively, and j = f, m. Here $e_t^r = 1, ..., 5$ corresponds to the five education levels in ascending order, X_t is work experience, and H_t is health.

3.4. Health Status

3.5. *The Marriage Market*

Putting this all together, the marriage offer for a single female consists of the vector

$$\mathcal{M}_{ft} = (E^m, H^m, X^m, N^m, PE^m, h_{t-1}^m, \mu_{mt}, \mu_m^W, \tilde{\varepsilon}_{mt}^W, \varepsilon_t^M). \tag{26}$$

Marriage offers for males (\mathcal{M}_{mt}) have an analogous form.

Given a marriage offer \mathcal{M}_{jt} , a single person can construct the vector $(\Omega_{ft}, \Omega_{mt})$ that characterizes the state of the couple if they marry. That is, $(\Omega_{jt}, \mathcal{M}_{jt}) \to (\Omega_{ft}, \Omega_{mt})$ for j = f, m. The potential partner also knows $(\Omega_{ft}, \Omega_{mt})$. Both parties calculate the value of marriage, denoted by $V_t^{jM}(\Omega_{mt}, \Omega_{ft})$ for j = f, m in equation (12). A marriage is formed if and only if

$$V_t^{fM}(\Omega_{mt}, \Omega_{ft}) > V_t^f(\Omega_{ft})$$
 and $V_t^{mM}(\Omega_{mt}, \Omega_{ft}) > V_t^m(\Omega_{mt}).$ (27)
