Identifying Policy Parameters

- Commonly used specifications

$$Y_1 = \mu_1(X) + U_1, \quad Y_0 = \mu_0(X) + U_0, \quad C = \mu_C(Z) + U_C, \quad (1)$$

where (X, Z) are observed by the analyst, and U_0, U_1, U_C are unobserved.

- Define Z to include all of X .
- Variables in Z not in X are instruments.
- $Z \perp\!\!\!\perp (U_0, U_1, U_C) | X$
- $I_D = E(Y_1 - Y_0 - C | \mathcal{I}) = \mu_D(Z) - V$
 $\mu_D(Z) = E(\mu_1(X) - \mu_0(X) - \mu_C(Z) | \mathcal{I})$
 $V = -E(U_1 - U_0 - U_C | \mathcal{I}).$
- Choice equation:

$$D = 1(\mu_D(Z) > V). \quad (2)$$

- In the early literature that implemented this approach $\mu_0(X)$, $\mu_1(X)$, and $\mu_C(Z)$ were assumed to be linear in the parameters, and the unobservables were assumed to be normal and distributed independently of X and Z .

Useful fact (previously discussed):

$$\begin{aligned}\text{Choice Probability : } P(z) &= \Pr(D = 1 \mid Z = z) \\ &= \Pr(\mu_D(z) \geq V) \\ &= \Pr\left(\frac{\mu_D(z)}{\sigma_V} \geq \frac{V}{\sigma_V}\right)\end{aligned}$$

$$\begin{aligned}P(z) &= F_{\left(\frac{V}{\sigma_V}\right)}\left(\frac{\mu_D(z)}{\sigma_V}\right) \\ U_D &= F_{\left(\frac{V}{\sigma_V}\right)}\left(\frac{V}{\sigma_V}\right); \quad \text{Uniform}(0, 1)\end{aligned}$$

$$\begin{aligned}
 P(z) &= \Pr \left(F_{\frac{V}{\sigma_V}} \left(\frac{\mu_D(z)}{\sigma_V} \right) \geq F_{\left(\frac{V}{\sigma_V} \right)} \left(\frac{V}{\sigma_V} \right) \right) \\
 &= \Pr (P(z) \geq U_D)
 \end{aligned}$$

$P(z)$ is the $p(z)^{\text{th}}$ quantile of U_D .

- It is also a monotonic transformation of the mean utility $\frac{\mu_D(z)}{\sigma_V}$
- So $P(z)$ is a monotonic transformation of utility

Recall

$$\begin{aligned}Y &= DY_1 + (1 - D)Y_0 \\&= Y_0 + D(Y_1 - Y_0)\end{aligned}$$

Keep X implicit (condition on $X = x$)

$$\begin{aligned}E(Y | Z = z) &= E(Y_0) + \underbrace{E(Y_1 - Y_0 | D = 1, Z = z)P(z)}_{\text{from law of iterated expectations}} \\&= E(Y_0) + E(Y_1 - Y_0 | P(z) \geq U_D)P(z)\end{aligned}$$

∴ It depends on Z only through $P(Z)$.

$$E(Y | Z = z') = E(Y_0) + E(Y_1 - Y_0 | P(z') \geq U_D)P(z')$$

Index Sufficiency

- **Question:** Why? Under what conditions?

- What is $E(Y_1 - Y_0 | P(z) \geq U_D)$? (Treatment on the treated)

Derivation

- Let the joint density of $(Y_1 - Y_0, U_D)$ be

$$f_{Y_1 - Y_0, U_D}(y_1 - y_0, u_D).$$

- It does not depend on Z .
- It may, in general, depend on X .
-

$$E(Y_1 - Y_0 | P(z) \geq U_D)$$

$$= \frac{\int\limits_{-\infty}^{\infty} \int\limits_0^{P(z)} (y_1 - y_0) f_{y_1 - y_0, U_D}(y_1 - y_0, u_D) du_D d(y_1 - y_0)}{\Pr(P(z) \geq U_D)}$$

- Recall that

$$U_D = F_{\left(\frac{V}{\sigma_V}\right)} \left(\frac{V}{\sigma_V} \right).$$

- U_D is a quantile of the V/σ_V distribution.

- By construction, U_D is Uniform(0, 1) (this is the definition of a quantile).
- $\therefore f_{U_D}(u_D) = 1$.
- Also, $\Pr(P(z) \geq U_D) = P(z)$.
- Notice, by law of conditional probability,

$$f_{Y_1 - Y_0, U_D}(y_1 - y_0, u_D) = f_{Y_1 - Y_0, U_D}(y_1 - y_0 \mid U_D = u_D) \underbrace{f_{U_D}(u_D)}_{=1}.$$

$$E(Y_1 - Y_0 \mid P(z) \geq U_D)$$

$$= \frac{\int\limits_0^{P(z)} \int\limits_{-\infty}^{\infty} (y_1 - y_0) f_{Y_1 - Y_0, U_D}(y_1 - y_0, u_D) d(y_1 - y_0) du_D}{P(z)}$$

$$E(Y_1 - Y_0 \mid P(z) \geq U_D)$$

$$= \frac{\int\limits_0^{P(z)} \int\limits_{-\infty}^{\infty} (y_1 - y_0) f_{Y_1 - Y_0, U_D}(y_1 - y_0 \mid U_D = u_D) d(y_1 - y_0) du_D}{P(z)}$$

$$= \frac{\int\limits_0^{P(z)} E(Y_1 - Y_0 \mid U_D = u_D) du_D}{P(z)}$$

- Definition: $E(Y_1 - Y_0 \mid U_D = u_d)$ is marginal treatment effect (MTE)
- If $P(z) = U_d$, agent with $Z = z$ is indifferent between “0” and “1”

$$\therefore E(Y | Z = z) = E(Y_0) + \int_0^{P(z)} E(Y_1 - Y_0 | U_D = u_D) du_D$$

$$\frac{\partial E(Y | Z = z)}{\partial P(z)} = \underbrace{E(Y_1 - Y_0 | U_D = P(z))}_{\text{EOTM or marginal gains for people with } U_D = P(z)}$$

$$E(Y | Z = z') = E(Y_0) + \int_0^{P(z')} E(Y_1 - Y_0 | U_D = u_D) du_D$$

- Consider mean of Y for two different values of Z
- Suppose $P(z) > P(z')$

$$\begin{aligned} & \therefore E(Y | Z = z) - E(Y | Z = z') = \\ &= \int_{P(z')}^{P(z)} E(Y_1 - Y_0 | U_D = u_D) du_D \\ &= E(Y_1 - Y_0 | P(z) \geq U_D \geq P(z')) \Pr(P(z) \geq U_D \geq P(z')) \end{aligned}$$

Notice

$$\begin{aligned}\Pr(P(z) \geq U_D \geq P(z')) &= \int_{P(z')}^{P(z)} du_D \\ &= P(z) - P(z') \\ E(Y | Z = z) - E(Y | Z = z') \\ &= E(Y_1 - Y_0 | P(z) \geq U_D \geq P(z'))(P(z) - P(z'))\end{aligned}$$

- This is LATE: will see why in next slides

$$\begin{aligned}
 & \frac{E(Y | Z = z) - E(Y | Z = z')}{P(z) - P(z')} = \text{LATE}(z, z') \\
 &= \frac{\int\limits_{P(z')}^{P(z)} \text{MTE}(u_D) du_D}{P(z) - P(z')}
 \end{aligned}$$
